(54) **Apparatus and method for making a contoured surface having complex topology**

(57) Apparatus for marking a contoured surface (30) having complex topology. The apparatus comprises a movable marker (50) for marking the surface and a sensor (60) disposed in sensing relationship to the surface for sensing contour of the surface. A controller (220) in-

terconnecting the marker and the sensor is also provided for actuating the marker and for controllably moving the marker relative to the surface in response to the contour sensed by the sensor, so that the marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.

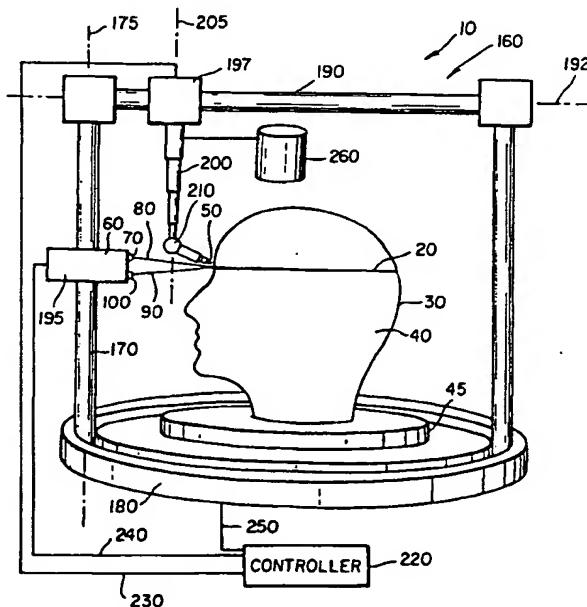

FIG. I

Description**BACKGROUND OF THE INVENTION**

[0001] This invention generally relates to marking apparatus and methods and more particularly relates to an apparatus and method for marking a contoured surface having complex topology.

[0002] It is often desirable to place an image on a three-dimensional object having a complex topology, such as a vase or a human bust statue. Usually this image is applied manually, which is timely and costly. Attempting to quickly apply the image manually to the object typically results in less precision in placement of the image on the object, which is an undesirable result. Therefore, it is desirable to provide a marking device capable of marking such a three-dimensional object having complex topology.

[0003] Devices for marking curved surfaces are known. One such device is disclosed in U.S. Patent No. 5,119,109 titled "Method And Apparatus For Marking The Inside Surface Of Pipe" issued June 2, 1992 in the name of John A. Robertson. This patent discloses a system wherein dot matrix characters are formed upon the inside surface of a pipe or other curved surface by an array of ink spray nozzles disposed within a marker head assembly. The marker head is moved by a carriage in a manner such that character pixels are formed during movement of the marker head along loci parallel with the longitudinal axis of the pipe. An indexing mechanism engages an outer surface of the pipe to index it from one marking locus to the next marking locus. Also, a translational mechanism moves the carriage from an off-line to an on-line position during operation of the device. However, this patent does not disclose measuring distance of the surface of the pipe from the marker head before marking begins. That is, this patent does not appear to disclose sensing distance of the surface from the marker head, which may be required in order to sequentially mark pipes having different diameters. Moreover, use of the Robertson device does not appear to assure uniform placement of ink on a contoured surface having complex topology, such as a vase or a human bust statue.

[0004] Therefore, an object of the present invention is to provide an apparatus and method for suitably marking a contoured surface of complex topology in a manner which automatically determines the contour of the surface and quickly, yet precisely, applies a marking medium uniformly to predetermined portions of the surface.

SUMMARY OF THE INVENTION

[0005] The present invention resides in an apparatus for marking a contoured surface having complex topology, characterized by a movable marker for marking the surface, a sensor disposed in sensing relationship to the surface for sensing contour of the surface; and a con-

troller interconnecting said marker and said sensor for actuating said marker and for controllably moving said marker relative to the surface in response to the contour sensed by said sensor, so that said marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.

[0006] In one aspect of the invention, the invention comprises an apparatus for marking a contoured surface having complex topology. The apparatus comprises a movable marker for marking the surface and a sensor disposed in sensing relationship to the surface for sensing contour of the surface. A controller interconnecting the marker and the sensor is also provided for actuating the marker and for controllably moving the marker relative to the surface in response to the contour sensed by the sensor, so that the marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.

[0007] A feature of the present invention is the provision of a sensor for sensing contour of the surface.

[0008] Another feature of the present invention is the provision of a controller connected to the sensor for obtaining a three-dimensional map of the surface sensed by the sensor.

[0009] An advantage of the present invention is that marking medium is precisely applied evenly on predetermined portions of the surface in a time-saving manner.

[0010] These and other objects, features and advantages of the present invention will become apparent to those skilled in the art upon a reading of the following detailed description when taken in conjunction with the drawings wherein there is shown and described illustrative embodiments of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] While the specification concludes with claims particularly pointing-out and distinctly claiming the subject matter of the present invention, it is believed the invention will be better understood from the following description when taken in conjunction with the accompanying drawings wherein:

[0012] 45 Figure 1 is a view in elevation of the present invention showing a sensor comprising a laser system for measuring distance of a contoured surface from the sensor;

[0013] 50 Figure 2 is a fragmentation view showing a telescoping arm connected to a printhead belonging to the present invention;

[0014] 55 Figure 3 is a view in elevation of the present invention showing a sensor comprising a ultra sound producing/detecting system for measuring distance of the contoured surface from the sensor;

[0015] Figure 4 is a view in elevation of the present invention showing a sensor comprising a mechanical follower for measuring distance of the contoured sur-

face from the sensor;
 Figure 5 is a view in elevation of an alternative embodiment of the invention;
 Figure 6 displays a logic flowchart of a process for mapping an image onto the surface; and
 Figure 7 is a continuation of the logic flowchart begun in Figure 6.

DETAILED DESCRIPTION OF THE INVENTION

[0012] The present description will be directed in particular to elements forming part of, or cooperating more directly with, apparatus in accordance with the present invention. It is to be understood that elements not specifically shown or described may take various forms well known to those skilled in the art.

[0013] Therefore, referring to Figs. 1, 2, 3 and 4, there is shown a first embodiment of the present invention, which is an apparatus, generally referred to as 10, for marking an image 20 on a contoured surface 30 defined by an object 40 resting on a support platform 45. Surface 30 may have a complex (i.e., undulating or curvilinear) topology. Apparatus 10 comprises a movable marker 50, which may be a piezoelectric inkjet printhead. Alternatively, printhead 50 may be a thermal inkjet printhead of the type disclosed in commonly assigned U.S. Patent Application Ser. No. 08/750,438 titled "A Liquid Ink Printing Apparatus And System" filed December 3, 1996, in the name of Kia Silverbrook. Referring again to Figs. 1, 2, 3 and 4, a sensor 60 is disposed in sensing relationship to surface 30 for sensing contour of surface 30. As sensor 60 senses contour of surface 30, the sensor 30 generates a contour map corresponding to the contour of surface 30 sensed thereby, as described more fully hereinbelow. Sensor 60 is preferably a laser system comprising a photodiode light source 70 capable of emitting a laser light beam 80 to be intercepted by surface 30 and reflected therefrom to define a reflected light beam 90. In such a laser system, sensor 30 further comprises a light detector 100, which may be a CCD (Charged Couple Device) associated with light source 70 for detecting reflected light beam 90. In this regard, the laser system comprising light source 70 and detector 100 may be a modified "IMPULSE™" model laser system available from Laser Technology, Incorporated located in Englewood, Colorado. Alternatively, sensor 60 may be a sound producing/detecting system comprising a sonic transducer 110 for emitting an ultra sound wave 120 to be intercepted by surface 30 and reflected therefrom to define a reflected sound wave 130. In such a sound producing/detecting system, sensor 60 further comprises a sonic detector 140 associated with transducer 110 for detecting reflected sound wave 130. In this regard, the sound producing/detecting system comprising sonic transducer 110 and sonic detector 140 may be a "Model 6500™" sound producing/detecting system available from Polaroid located in Cambridge, Massachusetts. As another alternative, sensor 60 may be a

mechanical follower mechanism comprising a telescoping spring-loaded follower 150 having an end portion 155 (e.g., a rollable ball bearing) adapted to contact surface 30 and follow therealong. In this case, telescoping follower 150 is capable of extending and retracting in order to follow contour of surface 30 and is also capable of generating an electrical signal indicative of the amount follower 150 extends and retracts with respect to contour of surface 30. It should be appreciated that sensor 60 and printhead 50 need not be pointing at the same location on surface 30 as long as the initial position of sensor 60 relative to the initial position of printhead 50 is known at the start of the mapping process.
 [0014] Still referring to Figs. 1, 2, 3 and 4, a positioning mechanism, generally referred to as 160, is connected to marker 50 and sensor 60 for positioning marker 50 and sensor 60 relative to surface 30. Positioning mechanism 160 comprises at least one elongate leg 170 defining a longitudinal first axis 175 therethrough. Leg 170 also has an end portion thereof connected to a motorized rotatable base 180 which rotates leg 170 in a 360° circle around support platform 45. The other end portion of elongate leg 170 is connected to an elongate beam member 190 defining a longitudinal second axis 192 therethrough disposed orthogonally (i.e., at a 90° angle) to first axis 175. Moreover, positioning mechanism 160 further comprises a motorized first carriage 195 which slidably engages leg 170 and to which sensor 60 is connected, so that sensor 60 is capable of slidably moving along leg 170 in the direction of first axis 175. In addition, positioning mechanism 160 comprises a motorized second carriage 197 which slidably engages beam member 190 and to which printhead 50 is connected, so that printhead 50 is capable of slidably moving along beam member 190 in the direction of second axis 192. More specifically, printhead 50 is connected to a telescoping arm 200 which in turn is connected to beam member 190. Connecting printhead 50 to arm 200 allows distance between printhead 50 and surface 30 to be held constant by adjustment of the amount of extension of arm 200. Maintaining constant distance between printhead 50 and surface 30 allows a marking medium (e.g., colored ink) to be uniformly applied to surface 30. To achieve this result, telescoping arm 200 is capable of telescoping printhead 50 outwardly away from and inwardly towards second carriage 197 along a third axis 205 running longitudinally through telescoping arm 200. Further, a ball-in-socket joint 210 preferably interconnects printhead 50 and arm 200 for moving printhead 50 in a path defined by a lune 215 centered about third axis 205 and circumscribing a 360° circle around arm 200, as best illustrated by dashed lines in Fig. 2. Ball-in-socket joint 210 is movable by means of a linkage (not shown) interconnecting ball-in-socket joint 210 with second carriage 197.
 [0015] Referring yet again to Figs. 1, 2, 3 and 4, it may be appreciated that printhead 50 obtains at least three degrees freedom of movement relative to surface 30 in

order to mark substantially any portion of surface 30. That is, printhead 50 is capable of moving around object 40 in a 360° circle to define a first degree freedom of movement because printhead 50 is connected to beam member 190 which in turn is connected to leg 170 that is connected to rotatable base 180. Thus, as rotatable base 180 moves leg 170 in the 360° circle around object 40, printhead 50 will also move to a like extent in a 360° circle around object 40. In addition, printhead 50 is capable of moving in a direction outwardly away from and inwardly towards second carriage 197 along third axis 205 to define a second degree freedom of movement. Moreover, printhead 50 is capable of moving, by means of ball-in-socket joint 210, in the path traveled by lune 215 to define at least a third degree freedom of movement. It is important that printhead 50 have at least three degrees freedom of movement. This is important in order to provide printhead 50 access to substantially any portion of surface 30 for marking substantially any portion of surface 30.

[0016] Referring again to Figs. 1, 2, 3 and 4, it may be appreciated that sensor 60 obtains two degrees freedom of movement relative to surface 30. That is, sensor 60 is capable of moving around object 40 in a 360° circle to define a first degree freedom of movement because sensor 60 is connected to leg 170, which in turn is connected to rotatable base 180. As previously mentioned, base 180 moves leg 170 in the 360° circle around object 40. In addition, sensor 60 is capable of moving in a direction along first axis 175 to define a second degree freedom of movement for sensor 60. It is important that sensor have at least two degrees freedom of movement. This is important to allow sensor 60 sufficient access to portions of surface 30 to be mapped by sensor 60 in the manner described hereinbelow.

[0017] Still referring to Figs. 1, 2, 3 and 4, a controller 220 is connected to printhead 50, sensor 60 and positioning mechanism 160 for controlling positioning of printhead 50 and sensor 60. With respect to controlling positioning of printhead 50, controller 220 is connected to second carriage 197, such as by means of a first cable 230, for activating second carriage 197, so that second carriage 197 controllably slides along beam member 190. As controller 220 activates carriage 197, controller 220 may also controllably activate arm 200 for telescoping printhead 50 along third axis 205 to a predetermined constant distance from surface 30. Further, as controller 220 activates arm 200, controller 220 may also controllably activate ball-on-socket joint 210, by means of the previously mentioned linkage (not shown), for moving printhead 50 in the path traveled by lune 215. Of course, a reservoir 260 is connected to printhead 50 for supplying the marking medium (e.g., colored ink) to printhead 50.

[0018] Again referring to Figs. 1, 2, 3 and 4, in order to control positioning of sensor 60, controller 220 is connected to first carriage 195, such as by means of a second cable 240, for activating first carriage 195, so that

first carriage 195 controllably slides along leg 170. Moreover, controller 220 is connected to base 180 for controlling rotation of base 180. More specifically, controller 220 is connected to base 180, such as by means of a third cable 250, for activating base 180, so that base 180 controllably rotates in the previously mentioned 360° circle around support platform 45 and thus around object 40. Moreover, controller 220 performs yet other functions. As described in detail hereinbelow, controller 220 stores image 20 therein, actuates sensor 60 to allow mapping contoured surface 30 as sensor travels about surface 30, and activates printhead 50 to apply image 20 to surface 30 according to the map of surface 30 stored in controller 220.

[0019] Therefore, referring to Figs. 1, 2, 3, 4, 6 and 7, the manner in which surface 30 is mapped into x, y and z Cartesian coordinates will now be described. First, object 40 is placed upon platform surface 45 by an operator of apparatus 10 as at Step 270. Either the operator or controller 220 then orients sensor 60 in the direction of object 40 as at Step 280. Next, controller 220 activates sensor 60 such that distance from sensor 60 of an initial point on surface 30 is determined as at Step 290. That is, sensor 60 effectively determines distance or proximity of object 40 from sensor 60. Distance of this initial point is determined either by use of light beams 80/90, sound waves 120/130 or follower 150. This initial point is designated as a datum point "0" and will have Cartesian coordinates of $x = 0$, $y = 0$ and $z = \text{distance from sensor 60}$ as at Step 300. These x, y and z coordinates for datum point "0" are then transmitted by second cable 240 to controller 220 and stored therein as at Step 310. Controller 220 then activates first carriage and/or base 180 to increment sensor 60 a predetermined amount in order to sense a first measurement point "1" on surface 30 as at Step 320. This first measurement point "1" is located at an epsilon distance " δ " on surface 30 in a predetermined direction from datum point "0" as at Step 330. Moreover, this first measurement point "1" will have coordinates of $x = x_1$, $y = y_1$ and $z = z_1$, where the values of x_1 , y_1 and z_1 are distances defining location of measurement point "1" from datum point "0" in the well-known three-dimensional Cartesian coordinate system as illustrated by Step 340. The coordinates of measurement point "1" are then transmitted by second cable 240 to controller 220 and stored therein as at Step 350. Controller 220 then activates first carriage and/or base 180 to increment sensor 60 epsilon distance " δ " to a second measurement point "2" on surface 30 as at Step 360. That is, this second measurement point "2" is located at the epsilon distance " δ " on surface 30 in a predetermined direction from first measurement point "1" as illustrated by Step 370. Moreover, this second measurement point "2" will have coordinates of $x = x_2$, $y = y_2$ and $z = z_2$, where the values of x_2 , y_2 and z_2 are distances defining separation of measurement point "2" from datum point "0" in the three-dimensional Cartesian coordinate system as illustrated by Step 380. These coordi-

nates of second measurement point "2" are then transmitted by second cable 240 to controller 220 and stored therein as at Step 390. In similar manner, controller 220 activates first carriage and/or base 180 to increment sensor 60 by increments equal to epsilon distance " δ " about the entire surface 30 to establish values of $x = 0, 1, \dots n_x$; $y = 0, 1, \dots n_y$; and $z = 0, 1, 2, \dots n_z$, where n_x , n_y and n_z equal the total number of measurement points to be taken on surface 30 in the x, y and z directions, respectively as at Step 400. Each measurement point is spaced-apart from its neighbor by epsilon distance " δ " as illustrated by Step 410. In this manner, all measurement points describing surface 30 are defined relative to initial datum point "0", which is defined by $x = 0$, $y = 0$ and $z = \text{distance from sensor 60}$ as illustrated by Step 420. The process disclosed hereinabove results in a three-dimensional grid map of contoured surface 30 being stored in controller 220 as x, y and z coordinates as at Steps 430, 440 and 450.

[0020] Referring again to Figs. 1, 2, 3 and 4, controller 220 performs a calculation which justifies image 20 stored therein with the x, y and z map of surface 30 as at Step 460. Preferably image 20 has been previously stored in controller 220 and represented therein in the form of a plurality of points defined by x' and y' two-dimensional Cartesian coordinates. That is, each point in image 20 stored in controller 220 has been previously assigned x' and y' values representing image 20 in an x'-y' two-dimensional plane. This x'-y' plane has an origin defined by values of $x' = 0$ and $y' = 0$. The values in the x'-y' plane range from $x' = 0, 1, 2, \dots n_x'$ and from $y' = 0, 1, 2, \dots n_y'$, where n_x' and n_y' equal the total number of pixel points representing image 20 in the x' and y' directions, respectively. Controller 220 then mathematically operates on the values defining the x'-y' plane of image 20 in order to justify the x' and y' values forming image 20 to the x and y measurement values forming the map of surface 30. That is, controller 220 multiplies each x' and y' value by a predetermined scaling factor, so that each x' and y' value is respectively transformed into corresponding x" and y" values as at Step 470. The z coordinates of the measurement values obtained by sensor 60 remain undisturbed by this justification. That is, after controller 220 scales the x' and y' values, controller 220 generates corresponding x" and y" values (with the z coordinate values remaining undisturbed). The x" values range from $x'' = 0, 1, 2, \dots n_x''$ and the y" values range from $y'' = 0, 1, 2, \dots n_y''$, where n_x'' and n_y'' equal the total of pixel points representing image 20 in the x" and y" directions, respectively as illustrated by Step 480. It should be understood from the description hereinabove, that once the values of x" and y" are defined, the values of z are predetermined because there is a unique value of z corresponding to each x" and y" pair as illustrated by Step 490. These values of x", y" and z define where ink pixels are to be applied on surface 30 as illustrated by Step 500. As described hereinbelow, after the map and image 20 stored in controller

220 are justified, controller 220 controls printhead 50 and positioning mechanism 160 to print the now justified image 20 on surface 30. If desired, the position of a significant portion (e.g., the nose on a bust statue) of image

5 20 in the x - y plane stored in controller 220 may be matched to the corresponding significant portion of object 40 stored in the x' - y' plane in order to obtain the necessary justification.

[0021] Again referring to Figs. 1, 2, 3 and 4, controller 10 220 transmits a signal to second carriage 197, arm 200, ball-in-socket joint 210 and/or base 180 to position printhead 50 at the first pixel point to be printed. This first 15 pixel point is located on surface 30 at a location defined by $x'' = 1$, $y'' = 1$ and the z value uniquely associated therewith. That is, once $x'' = 1$ and $y'' = 1$ are defined, the value of z corresponding to the pair of values for $x'' = 1$ and $y'' = 1$ is predetermined. Next, controller 220 20 activates printhead 50 to expel ink at the location on surface 30 corresponding to $x'' = 1$, $y'' = 1$ and the associated z value in order to mark surface 30 thereat. If desired, the z value is scaled such that printhead 50 is always spaced a predetermined distance from surface 30 in order to uniformly apply ink to surface 30. The process described hereinabove is repeated until all of image 20 25 is marked on surface 30.

[0022] As best seen in Fig. 5, an alternative embodiment of the present invention is there shown for marking contoured surface 30. In this alternative embodiment of the invention, printhead 50 and sensor 60 are combined 30 into one assembly. This alternative embodiment of the invention eliminates need for first carriage 195 and second cable 240. Instructions to both printhead 50 and sensor 60 are transmitted thereto from controller 220 over first cable 230. Moreover, this alternative embodiment of the invention allows sensor 60 to have the same number of degrees of freedom (i.e., at least three degrees of freedom) as printhead 50. This results in an increased number of degrees of freedom of movement for sensor 60 compared to the first embodiment of the 35 invention. This is particularly useful to facilitate measurement of surfaces which are largely perpendicular to third axis 205.

[0023] It may be appreciated from the teachings herein that an advantage of the present invention is that 40 marking medium is precisely applied evenly on predetermined portions of surface 30 in a time-saving manner. This is so because the automatic control provided by controller 220 allows printhead 50 to be spaced a constant distance from surface 30 by means of precise 45 movement of positioning mechanism 160 and also allows the speed of the marking process to be increased compared to the manual marking technique.

[0024] While the invention has been described with particular reference to its preferred embodiments, it is 50 understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements of the preferred embodiments without departing from the invention. For example, apparatus 10 is dis-

closed herein as applying ink on surface 30 to create a printed image; however, apparatus 10 may be modified to abrade predetermined portions of surface 30 to create an image in relief. As another example, apparatus 10 may be modified to apply a glaze or other protective coating to predetermined portions of surface 30. As yet another example, support platform 45 may be suitably rotated rather than base 180. As still another example, support platform 45 may be movable vertically. Also, although the Cartesian coordinate system is used to map surface 30, the Polar coordinate system may be used instead. As a further example, inkjet printhead 50 may be replaced by a suitable brush.

[0025] Therefore, what is provided is an apparatus and method for marking a contoured surface having a complex topology.

Claims

1. An apparatus for marking a contoured surface (30) having complex topology, characterized by:
 - (a) a movable marker (50) for marking the surface;
 - (b) a sensor (60) disposed in sensing relationship to the surface for sensing contour of the surface; and
 - (c) a controller (220) interconnecting said marker and said sensor for actuating said marker and for controllably moving said marker relative to the surface in response to the contour sensed by said sensor, so that said marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.
2. The apparatus of claim 1, further characterized by a positioning mechanism (160) interconnecting said controller and said marker for controllably carrying said marker with respect to the surface.
3. The apparatus of claim 1, wherein said marker is an inkjet printhead.
4. The apparatus of claim 1, wherein said sensor is characterized by:
 - (a) a light source (70) for emitting a light beam (80) to be intercepted by the surface and reflected therefrom to define a reflected light beam (90); and
 - (b) a light beam detector (100) associated with said light source for detecting the reflected light beam.
5. The apparatus of claim 1, wherein said sensor is characterized by:
 - (a) a sound emitter (110) for emitting a sound wave (120) to be intercepted by the surface and reflected therefrom to define a reflected sound wave (130); and
 - (b) a sound detector (140) associated with said sound emitter for detecting the reflected sound wave.
6. The apparatus of claim 1, wherein said sensor is characterized by a follower (150) adapted to contact the surface and follow the contour of the surface.
7. A method of marking a contoured surface (30) having complex topology, characterized by the steps of:
 - (a) disposing a movable marker (50) relative to the surface for marking the surface;

(b) disposing a sensor (60) in sensing relationship to the surface for sensing contour of the surface; and
(c) interconnecting a controller (220) to the marker and the sensor for actuating the marker and for controllably moving the marker relative to the surface in response to the contour sensed by the sensor, so that the marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.

5

10

8. The method of claim 7, further characterized by the step of interconnecting a positioning mechanism (160) to the controller and the marker for controllably carrying the marker with respect to the surface.

15

9. The method of claim 7, wherein the step of disposing the marker relative to the surface characterized by the step of disposing an inkjet printhead relative to the surface.

20

10. The method of claim 7, wherein the step of disposing the sensor is characterized by the steps of:

25

(a) emitting a light beam (80) from a light source (70), the light beam being intercepted by the surface and reflected therefrom to define a reflected light beam (90); and
(b) detecting the reflected light beam using a light beam detector (100) associated with the light source.

30

11. The method of claim 7, wherein the step of disposing the sensor is characterized by the steps of:

35

(a) emitting a sound wave (120) from a sound emitter (110), the sound wave being intercepted by the surface and reflected therefrom to define a reflected sound wave (130); and
(b) detecting the reflected sound wave using a sound detector (140) associated with the sound emitter.

40

12. The method of claim 7, wherein the step of disposing the sensor is characterized by the step of following the contour of the surface using a telescoping follower (150) adapted to contact the surface and follow therealong.

(54) **Apparatus and method for making a contoured surface having complex topology**

(57) Apparatus for marking a contoured surface (30) having complex topology. The apparatus comprises a movable marker (50) for marking the surface and a sensor (60) disposed in sensing relationship to the surface for sensing contour of the surface. A controller (220) interconnecting the marker and the sensor is also provided for actuating the marker and for controllably moving the marker relative to the surface in response to the contour sensed by the sensor, so that the marker follows the contour of the surface at a predetermined distance therefrom and marks the surface.
